After the second microPET scan, the cortical ^11^C radioactivity had increased to 0.5 and 0.6 for Chol-^4 and Chol-^5, respectively. MicroPET scans using the thio-analogues of ^1, Chol-^2 and Chol-^3 were of similar quality (data not shown). Discussion ===== We have been able to introduce ^18^F-labelled cholesteryl anchor structures, with up to three potential PEGylation sites, directly into the alkyne-containing parent structure. These new structures were ^18^F-labelled under mild conditions in acceptable radiochemical yields and ^in vitro stability. The cholesteryl anchors were then assessed for their ^in vitro and ^in vivo performance as PET tracers for ^β-AR imaging in rats. ^In vitro receptor binding assays using a whole brain homogenate of pituitary adenylate cyclase activating polypeptide-expressing GH~3~ cells provided ^K~i~ values in the nanomolar range for all radiotracers. Interestingly, the affinity values were lower than the ^K~d~ values obtained for the non-labelled compounds (from 0.4 to 1.0 μM) ([@aws019-B5]), suggesting some type of competition at the ^β-AR or a competitive inhibition mechanism of the radiotracer. The competition may be due to the presence of (a) a cholesteryl anchor structure (which includes two PEG chains), (b)
