This ERC-CoG award will provide me with the time to develop the necessary skills as a patient-oriented researcher. My long-term career goals are to establish a career in patient-oriented research with a focus on depression in the genetic and epigenetic realm. I am developing a portfolio of research that will consist of investigation into the influence of psychosocial stress exposure and genotype on depressive symptomology, suicidality, and cognition. This research will be accomplished through investigation of the role of serotonin transporter promoter genotype (SERT), cortisol, and psychosocial stress exposure on cognitive flexibility and executive functioning. A total of 200 patients with major depression and 125 healthy controls will complete a detailed assessment of cognitive flexibility and executive functioning. In addition, a twin study design will be employed to examine the relative contribution of shared environmental and genetic factors to depressive symptomology and suicidality. It is my intention to utilize results of the proposed research to develop a more detailed conceptual model regarding the relationship between serotonin transporter promoter genotype, cortisol levels, and psychosocial stress exposure and depression. Such a model may be used to predict and explain the effects of future treatment conditions that attempt to target serotonin signaling. Findings will also potentially allow for more personalized and rational treatment of depression through the use of genetic screening. Depression is currently a major public health concern. Psychiatric medication treatment approaches are successful in many cases, but are known to cause undesirable effects as well as require an extended time course. The advent of genetic screening allows for a more efficient and personal treatment approach. Relevance to public health: Depression is the most prevalent psychiatric disorder, with only half of those suffering from depression being successfully treated. The results of this proposed research may lead to
